P1-256

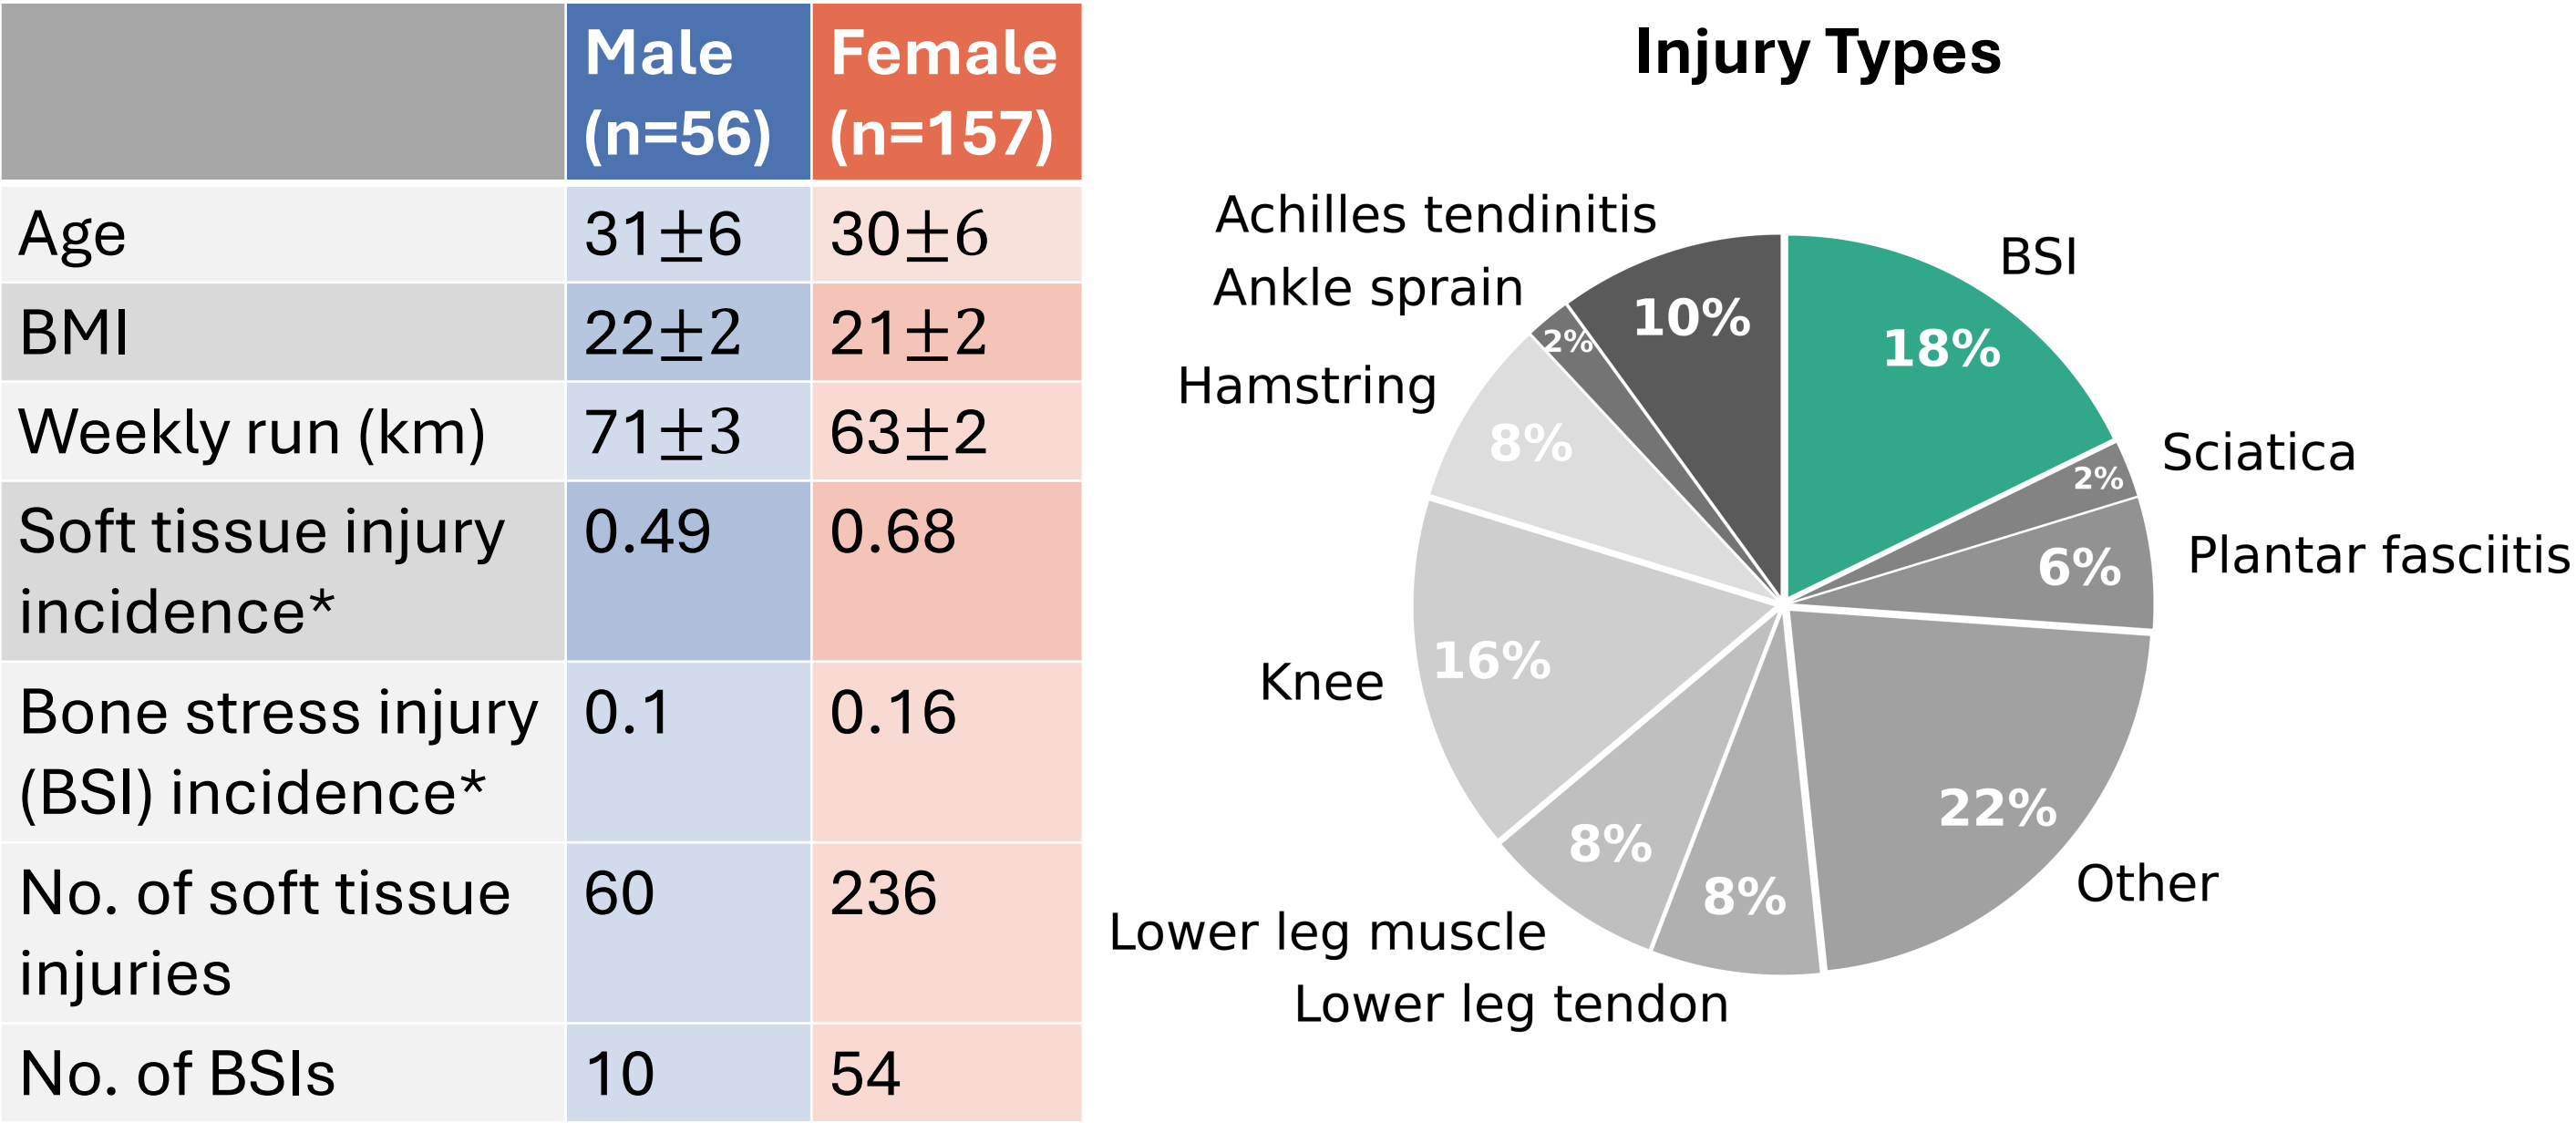

Motivation

- GPS-enabled smartwatches provide large-scale physiological and biomechanical data that could help guide injury prevention for runners.
- We quantify the trade off between running performance and injury risk in a large, real-world cohort.

Methods

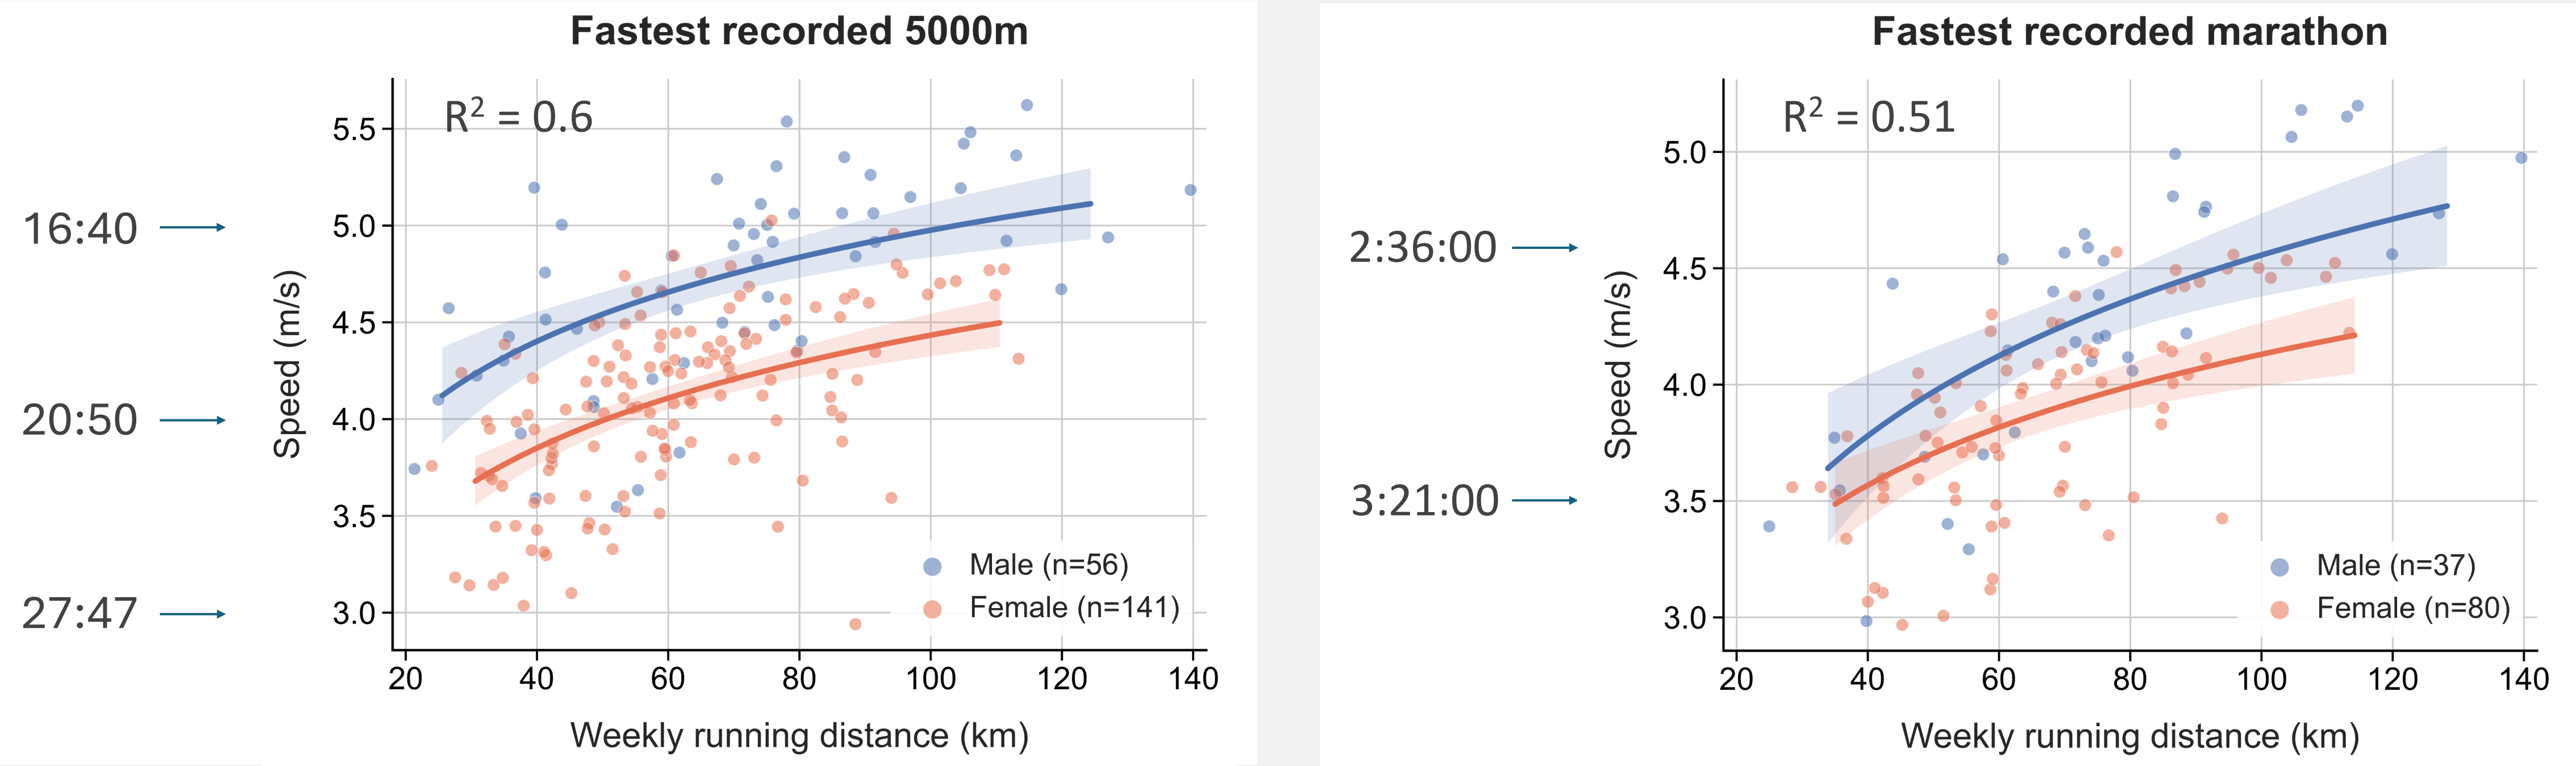

Cohort

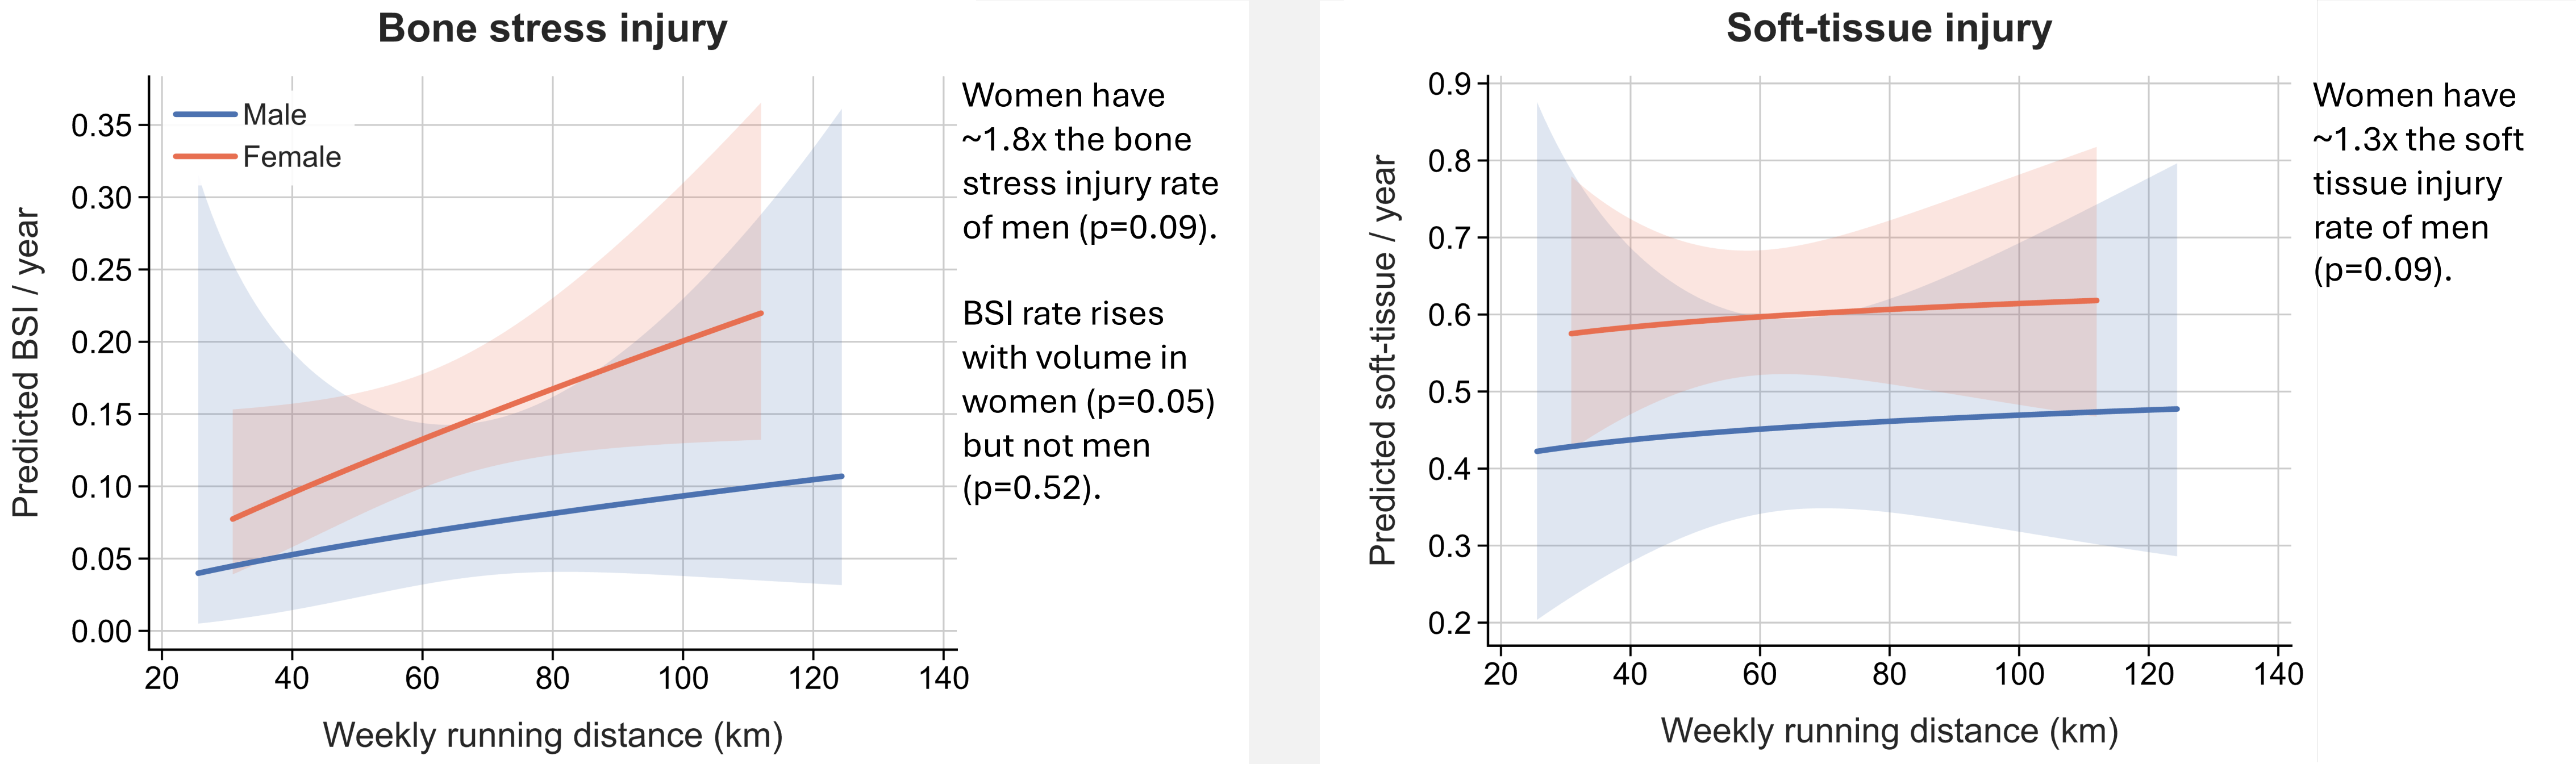

Results

Mean fastest recorded 5000m: 16:22 18:44

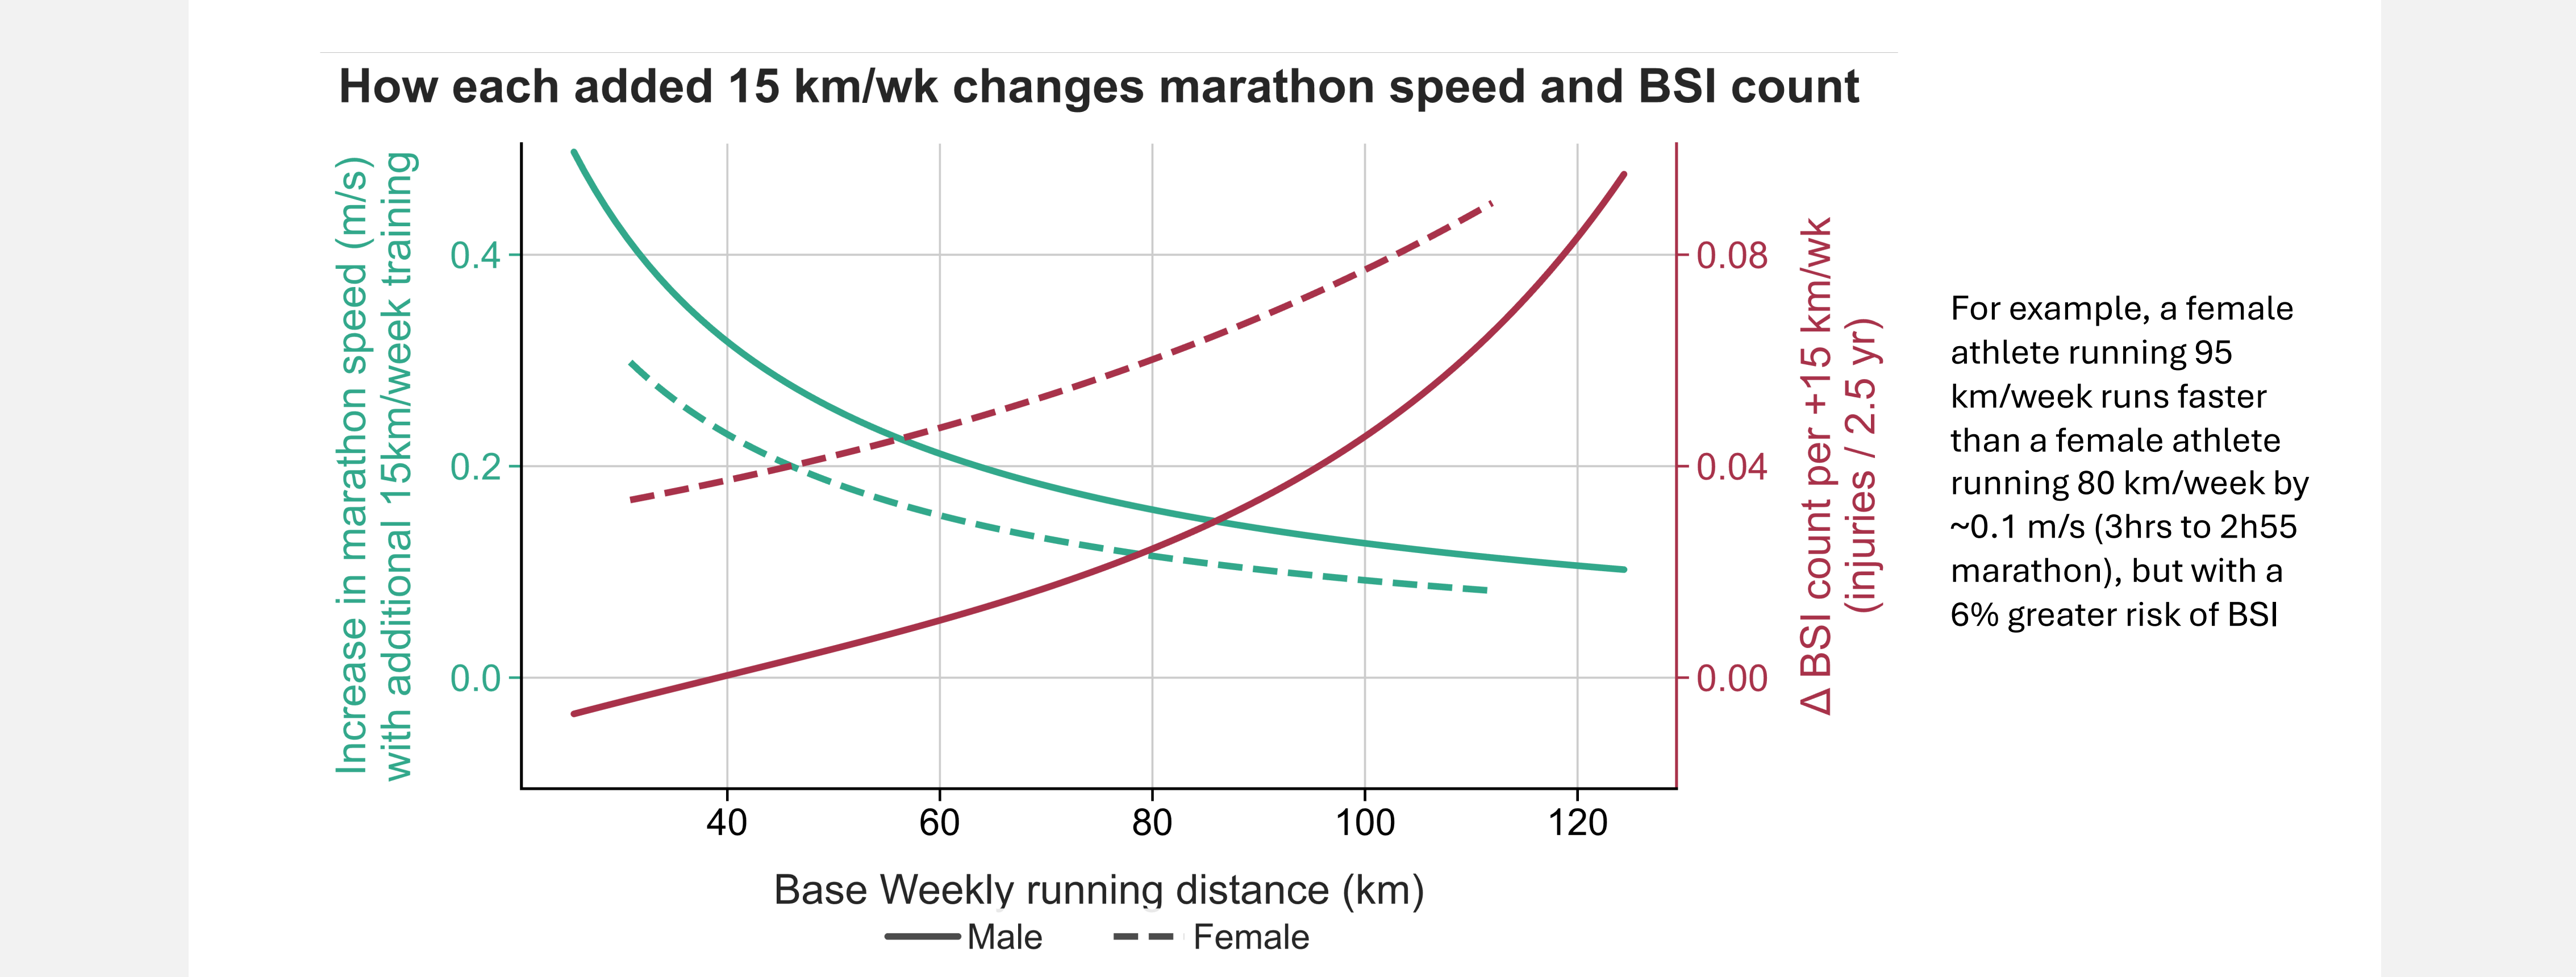

Training volume was associated with faster 5k and marathon speeds

Training volume was associated with bone stress injury, but not soft tissue injury rates

Higher mileage is associated with increased rates of BSI, along with improved performance, but diminishing returns

Wearables can quantify the interaction between training, injury risk, and performance with unprecedented granularity. Future work adding menstrual status may further inform training and injury risk.
